

Record 9 - Alpine Orthopedic Surgery - Operative Report

Date of Service: 05/12/2026

Surgeon: Dr. R. Whitfield, MD

PREOPERATIVE DIAGNOSIS: Full-thickness right rotator cuff (supraspinatus) tear.

POSTOPERATIVE DIAGNOSIS: Same, with moderate tendon retraction and fraying noted intraoperatively, more advanced than typical for an acute tear given the delay to surgical repair.

PROCEDURE: Right shoulder arthroscopy with rotator cuff repair.

FINDINGS: Full-thickness supraspinatus tear confirmed, moderate retraction requiring extensive mobilization to achieve primary repair. Mild-to-moderate fatty infiltration of the supraspinatus muscle belly noted. Repair performed successfully using suture anchor technique.

Patient tolerated the procedure well.
